("Read the manuals" in Italian)

Resources on Syntax

- ▶ Julia Official Tutorial: https://julialang.org/learning/tutorials/
- ► Wikibook on Introducing Julia: https://en.wikibooks.org/wiki/Introducing_Julia
- ► QuantEcon w/ Julia: https://julia.quantecon.org/intro.html
- ▶ Julia in 100 Seconds: https://www.youtube.com/watch?v=JYs_94znYyo

The REPL

REPL stands for **R**ead, **E**valuate, **P**rint, and **L**oops.

Julia's REPL is the best I have ever seen, includes

- lacktriangle Unicode transformation: type \arrowvert alpha and \arrowvert ab leads to lpha
- ▶ Package management: type] to enter Pkg mode to add packages
- ▶ Manual query: type ? to enter help mode & find function manual
- ▶ Tab completion: type \al and tab gives you possible commands
- $ightharpoonup \uparrow / \downarrow$: up/down arrow key cycle through executed command history

The Language: Good and Bad

Julia language is designed with scientific computing in mind, and thus

- ightharpoonup Unicode variable: directly use lpha as variable, not **alpha** .
- ▶ Multiple dispatch: multiple "methods" in one function for input types
- ▶ Type system: use | struct to build custom types (\approx but \neq OOP)

But also have some weird behavior that I am not used to:

- ▶ Weird scope: variables defined inside loops (while , for) are local.
- ▶ Speed needs discipline: well-written code v.s. sloppy-written code
- ▶ Memory usage: might directly crash the Julia session (∵ LLVM?)

Best practice?

Still Searching...

4 Gov Spending

Syntax: generating a grid

- ▶ Usually the Macro coding starts with the grids of choice variables.
- ▶ A grid is a finite sample of continuous choice variable.
- ▶ Key to construct a grid is the collect and range function.
- ▶ range syntax requires start pt, stop pt and length of this grid
- ▶ collect then "collect" this range object into an array.

```
cnum = 100
lnum = 100
cgrid = collect( range( 0.01, 10.0, length = cnum ) )
lgrid = collect( range( 0.01, 1.0, length = lnum ) )
```

Syntax: Array manipulation

To get one element of a grid, we use [] syntax.

```
cval = cgrid[1] # get the first element of cgrid
lval = lgrid[5] # get the fifth element of lgrid
```

To create an array, you can use manual or automatical way.

```
# manually type all the elements
a = [1.0, 2.0, 3.0, 4.0, 5.0]
# automatically generate an "empty" array
# type dim empty row column
utility = Array{Float64, 2}(undef, cnum, lnum)
utility = zeros(cnum, lnum) # zero array
utility = ones(cnum, lnum) # one array
```

Syntax: for loop

To calculate the utility value at each (C, I) bundle, use **for** loop

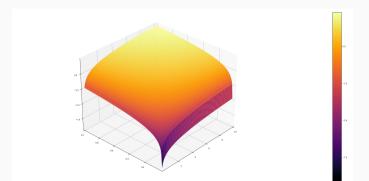

```
utility = Array{Float64, 2}(undef, cnum, lnum)
for indl in 1:1:lnum
    # get the each value in leisure grid
    lval = lgrid[indl]
    for indc in 1:1:cnum
        # get the each value in consumption grid
        cval = cgrid[indc]
        # log utility in both c and l
        utility[indc, indl] = log(cval) + log(lval)
    end
end
```

Gov spending

Syntax: 3-D plotting

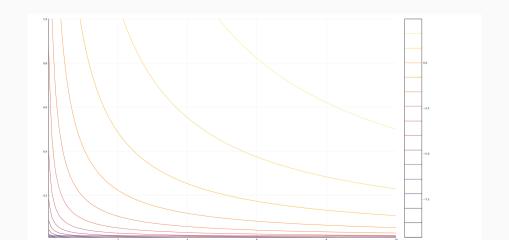

```
Install Plots and PyPlot by typing ] and type add Plots PyPlot
Plot the utility array by
```

```
using Plots; pyplot();
surface(cgrid, lgrid, utility) # 3-D figure
```

Syntax: contour plotting

```
using Plots; pyplot();
contour(cgrid, lgrid, utility) # contour figure
```

Syntax: println print something out

To show some info inside the **for** loop, **println** is a convenient tool. If you want to know what (C, I) bundle leads to U(C, I) = 0.0,

```
for indl in 1:1:lnum
    for indc in 1:1:cnum
        # the abs of u is close enough to 0.0
        if abs(utility[indc, indl]) < 1e-2
        # '$': string interpolation (IMO inefficient)
            println("U ~ 0 at (C, l) = ($indc, $indl)")
        end
    end
end</pre>
```

println v.s. print: println add additional \n

Syntax: while loop

```
In my experience it is mostly used if something needs convergence.
The following code is NOT an efficient way to find minimum location.
(should use argmin for minimum and argmax for maximum)
    dist = 1.0: iter = 0:
    while (dist > 1e-2)
         iter += 1  # same as "iter = iter + 1"
         indc = rand(1:1:cnum); indl = rand(1:1:lnum)
         dist = utility[indc, indl] - minimum(utility)
         if (dist < 1e-2)
             println("Find minimum at ($indc, $indl)")
             println("Iterates $iter times")
         end
     end
```

while loop mostly used when iteration only hault in some conditions.

Syntax: Rounding

Mostly for exam / standardization purpose.

```
round(pi) # 3.0
round(pi, digits = 1) # 3.1
round(pi, digits = 2) # 3.14
round(pi, digits = 3) # 3.142
round(pi, digits = 4) # 3.1416
round(pi, digits = 5) # 3.14159
```

Outline

- 1 Basic Julia Usage
- 2 Syntax
- 3 Laffer curve
- 4 Gov Spending

Application: Laffer curve

There are going to be two applications for Julia syntax learned:

- 1 Laffer curve in distorting taxes, and
- 2 Government spending in CRRA utility function.

Recall that $Y = zN^d$ implies labor supply $N^s(t)$ equals to

$$N^{s}(t) = 1 - I = \frac{1}{2} - \frac{\pi}{2(1-t)},\tag{1}$$

and the total tax revenue is given by

$$R(t) = wtN^{s}(t). (2)$$

In equilibrium w=z=1, so $\pi=zN^d-wN^d=0$, so this question is trivial...

Laffer curve in Cobb-Douglas Production Function

Assume $Y = zN^a$, where a < 1, so firm's problem leads to

$$w(N) = MPN = zaN^{a-1},$$
 (3)
 $\pi(N) = Y - wN = z(1-a)N^{a}.$ (4)

and recall $MRS_{I,C} = w(1-t)$ and binding BC $C = w(1-t)N + \pi$, so

$$MRS_{I,C} = \frac{C}{I} = \frac{w(1-t)N + \pi}{I} = w(1-t)$$

$$= \frac{w(N)(1-t)N + \pi(N)}{(1-N)} = w(N)(1-t)$$
(5)

expands, we get a monster:

$$\frac{zaN^{a-1}(1-t)N + z(1-a)N^a}{1-N} = zaN^{a-1}(1-t)$$
 (7)

Laffer curve in Cobb-Douglas Production Function (cont.)

But not too bad, because you realize:

Common
$$zN^{a}$$
:
$$\frac{zaN^{a}(1-t)+z(1-a)N^{a}}{1-N} = zaN^{a-1}(1-t)$$
(9)
Erase zN^{a-1} :
$$\frac{zN^{a}[a(1-t)+1-a]}{1-N} = za(1-t)N^{a-1}$$
(10)
Divide $[\cdot]$:
$$\frac{N[a(1-t)+1-a]}{1-N} = a(1-t)$$
(11)
$$\frac{N}{1-N} = \frac{a(1-t)}{a(1-t)+1-a} \equiv A(t)$$
(12)
$$N = A(1-N) = A - AN$$
(13)
$$(1+A)N = A \Rightarrow N(t) = \frac{A(t)}{1+A(t)}$$
(14)

Common N: $\frac{zaN^{a-1}(1-t)N + z(1-a)N^a}{1-N} = zaN^{a-1}(1-t)$

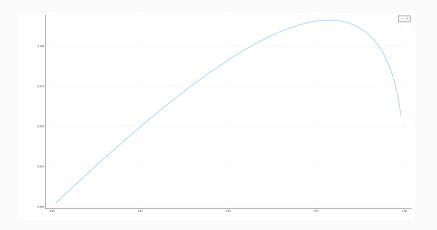

(8)

Laffer curve in Julia

```
a = 0.33: tnum = 1000
tgrid = collect( range(0.01, 0.99, length = tnum) )
Gvec = Array{Float64, 1}(undef, tnum)
for indt = 1:1:tnum
    t = tgrid[indt]
   A = (a*(1-t)) / (a*(1-t) + 1 - a)
   N = A / (1 + A)
   w = a*N^{(a-1)}
    Gvec[indt] = w * t * N
end
Gmax = maximum(Gvec); tmax = tgrid[argmax(Gvec)];
println("G* = $Gmax; t* = $tmax")
```

Laffer curve in Julia (cont.)

```
using Plots; pyplot()
plot(tgrid, Gvec, label = "G")
```

- 4 Gov Spending

Grid search

Just calculate value **on** the grid points! Like **Profile** slide

Recall the formula with gov spending:

$$\max_{l} \quad \frac{(z(1-l)^{1-\alpha}-G)^{1-b}}{1-b} + \frac{l^{1-d}}{1-d}. \tag{15}$$

We want to solve I(z, G), but how to choose the Ggrid?

From the FOC we know

$$G = F(I) = z(1 - I)^{1 - \alpha} - \left[\frac{I^{-d}}{(1 - \alpha)z(1 - I)^{-\alpha}} \right]^{-\frac{1}{b}}.$$
 (16)

Our first step starts with generating a TFP grid:

```
znum = 100
zgrid = collect( range( 0.8, 1.2, length = znum ) )
```

Grid search: preperation

We want to find the upper/lower bound of ${\tt Ggrid}:$

```
a = 1/2; b = 2; d = 3/2;
GovFOC(z, l) = z*(1-l)^(1-a) - \# line continuation!
    ((1^{(-d)}) / ((1-a)*z*(1-1)^{(-a)}))^{(-1/b)}
# upper & lower bound of Ggrid
Gbound = Array{Float64, 2}(undef, znum, 2)
for indz = 1:1:znum
    zval = zgrid[indz]
    Gbound[indz, 1] = GovFOC(zval, 0.99) # lower bound
    Gbound[indz, 2] = GovFOC(zval, 0.01) # upper bound
end
```

Grid search: preperation (cont.)

```
# lower bound should higher than 0.01
Glow = max(0.0, minimum(Gbound))
Ghigh = maximum(Gbound)
# build Ggrid
Gnum = 100
Ggrid = collect( range( Glow, Ghigh, length = Gnum ) )
# build lgrid
1 \text{ num} = 100
lgrid = collect( range( 0.01, 1.0, length = lnum ) )
```

and then find the optimal leisure using the value on this grid:

Grid search: structure

```
a = 1/2; b = 2; d = 3/2;
# define implicit utility function
utility(l, z, G) = ((z*(1-l)^{(1-a)} - G)^{(1-b)})
                   (1-b) +
                   (l^{(1-d)})/(1-d)
# Arrav for storage
## for temporary storage
uvec = Array{Float64, 1}(undef, lnum)
## for optimal utility value
ustar = Array{Float64, 2}(undef, znum, Gnum)
## for optimal leisure given z, G
lstar = Array{Float64. 2}(undef. znum. Gnum)
```

Grid search: structure (cont.)

```
for indG = 1:1:Gnum
    Gval = Ggrid[indG]
    for indz = 1:1:znum
        zval = zgrid[indz]
        for indl = 1:1:lnum
            lval = lgrid[indl]
            cval = zval*(1-lval)^{(1-a)} - Gval
            uvec[indl] = (cval < 0.0 ? -Inf :
                             utilitv(lval, zval, Gval) )
        end
        ustar[indz. indG] = maximum(uvec)
    end
end
```

Grid search: analysis

Notice that in previous slide, I check whether cval < 0.0 and also we find the highest utility and the corresponding (z, G) value by

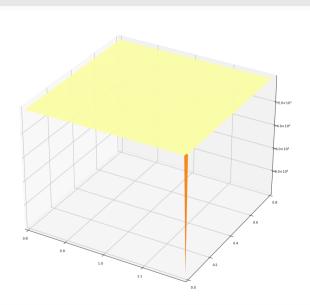

```
umax = maximum(ustar)
zloc = argmax(ustar)[1]
Gloc = argmax(ustar)[2]
zmax = zgrid[zloc]
Gmax = Ggrid[Gloc]
```

But if you plot you will see that the plot is slightly "off":

```
using Plots; pyplot()
surface(zgrid, Ggrid, ustar)
```

: large negative point that drag down the scale of every point.

grid search: misleading figure

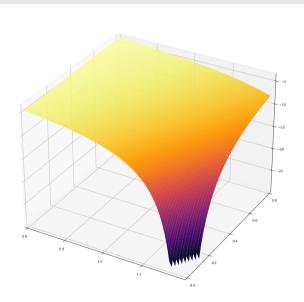

25/32

-2.0×10⁴

Grid search: revising (erase uval < -30.0)

```
for indG = 1:1:Gnum
    Gval = Ggrid[indG]
    for indz = 1:1:znum
        zval = zgrid[indz]
        for indl = 1:1:1num
            lval = lgrid[indl]
            cval = zval*(1-lval)^{(1-a)} - Gval
            uval = utility(lval, zval, Gval)
            uvec[indl] = ((cval < 0.0 || uval < -30.0)
                            ? -Inf : uval )
        end
        ustar[indz, indG] = maximum(uvec)
    end
end
```

Grid search: better figure

Grid search: Can we do better?

```
All of the -Inf stuff we are assigning manually is because C < 0.
Recall that C = Y - G and thus for C > 0, Y - G > 0 \Rightarrow Y > G.
     vmat = Array{Float64. 2}(undef. znum. lnum)
     for indl = 1:1:lnum
         lval = lgrid[indl]
          for indz = 1:1:znum
              zval = zgrid[indz]
              ymat[indz, indl] = zval * (1-lval)^(1-a)
          end
     end
     vmin = minimum(vmat)
```

You will get min(y) = 0.081, which means that if you choose the Ghigh = 0.08, $C > 0, \forall z, G$ assigned.

Grid search: do better

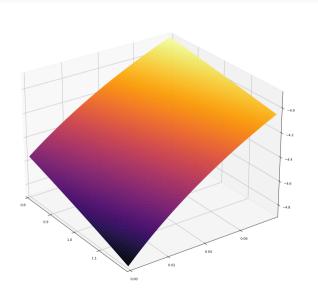

```
# lower bound should higher than 0.01
Glow = 0.0
Ghigh = 0.08
# build Ggrid
Gnum = 100
Ggrid = collect( range( Glow, Ghigh, length = Gnum ) )
# build lgrid
lnum = 100
lgrid = collect( range( 0.01, 0.99, length = lnum ) )
```

and then find the optimal leisure using the value on this grid:

Grid search: do better (cont.)

```
for indG = 1:1:Gnum
    Gval = Ggrid[indG]
    for indz = 1:1:znum
        zval = zgrid[indz]
        for indl = 1:1:lnum
            lval = lgrid[indl]
            cval = zval*(1-lval)^{(1-a)} - Gval
            uvec[indl] = utility(lval. zval. Gval)
        end
        ustar[indz, indG] = maximum(uvec)
    end
end
```

Grid search: better figure

Grid search method: additional details

Calculate on the grid point \Rightarrow result are correct but speed is slow.

Notice that when you choose the grid points, better to avoid some value:

Example

When I create \mbox{cgrid} and \mbox{lgrid} , I avoid the start point of 0.0, but 0.01, since $\mbox{log}(0.0) = \infty$.

In general, if theoretical range, say leisure, is [0,1], then it is safe to build a grid from [0.01, 0.99].
